SPRINT 2 REVIEW

For Sprint 2, our team spent time researching how to make our web application functional using the right technologies. We explored various tools and frameworks that could connect the frontend with a backend service, comparing their features, ease of use, and how well they could support authentication and data storage. We wanted to find a solution that was reliable, beginner-friendly, and would allow our team to build a complete full-stack web app efficiently.

Our team met with our professor to get confirmation for our project idea and to discuss some potential user stories. During the meeting, he asked what technologies we planned to use, and at the time, we didn't have a clear or valid idea of how to implement our project. After explaining our goals, he suggested a few tools that would be extremely helpful moving forward. He recommended that we build the frontend using React and use Firebase for both the backend and database, since it could handle authentication, data storage, and hosting all in one platform.

Following his advice, we focused our Sprint 2 efforts on setting up Firebase Authentication for user sign-in and sign-out, and on preparing the app for deployment using Firebase Hosting. This meeting really helped clarify our project direction and gave us confidence that we were choosing the right tools for our sprint goal.

Near the end of sprint 2 and after our meeting with Professor Doran, our team coded in an authentication part to our program. This takes in an email and password to give users access to the program itself. It also includes a portion that takes in an email and a valid password to allow users to properly sign up and create an account that is recorded in the database. Through this there is a layer of authentication for users so that we can differentiate the users information so that they can get the right information displayed.

One of the roadblocks or challenges we ran into was time constraints. We couldn't do much since our meeting happened so late in our sprint. Before the meeting we didn't really fully have an understanding on what we were going to use for the project. Because of the meeting, it allowed us to get an understanding and at least create a base for the project with authentication even with the small amount of time that we had.

We didn't get much "client/stakeholder" feedback from this sprint which might be an issue in the future. Hopefully we can try to schedule another meeting to try and get some feedback with a proper demonstration. What feedback we got though was finding out to use React and Firebase to properly create the project and continue development through the next sprint. In sprint 3 we hope to get a functional demo out that works properly.
