Sprint 4 Reflection Andrew Kim

For the fifth sprint, I created the functions that are mainly needed to send bulk files and save them into the Firestore Database, specifically in our case the SUBTLEX file. I also worked on sending the information to the Firestore Database and being able to use that data in our code. One of the biggest issues that I ran into while working on this project was the limits of what the free tier of firebase would allow. Firestore Database limits the amount of reads, writes, and deletes you get per day if you have the free version and sometimes will block you out of the entire database if you go over the quota. Because of this we had to find some workarounds for some of these things. One of the ways was separating files into smaller pieces to upload it over the course of multiple days. By doing this we could get all of our bigger files fully stored into firebase. This is not ideal because using multiple days to just store things is time that we don't have especially with barely 1 sprint left. The other choice would be to use a different database or pay a lot of money for more reads and writes. If there's anything that I've learned is that storage is extremely important when it comes to projects like this, especially when there is no budget for any premium options. The free tier of firebase is not ideal for a project like ours because we cannot test it as much as we want and are limited. It's very hindering but it's the best we can do when there is no funding. If it wasn't so expensive I might have considered paying a bit for more but at that point we could have used something like the firebase storage which can just take in files instead of having to move everything into a database. Most of the time I just use as much storage to save time but being limited is a situation I did not think would become an issue. The final sprint is going to be very difficult and I'm very anxious and worried about the finished product.
